Earthquakes are one of most devastating natural disasters. It occurs abruptly without any warnings. Devastating earthquake occurred in Nepal on 25th April 2015 at 11:56 AM. It measured 7.8 Richter scale.¹⁰ Epicenter was on the east of Lamjung and hypocenter was at around only 15 kilometers depth. The epicenter was around 80 kilometers northwest of the capital Kathmandu. It killed more than 8964 and injured more than 21952 people⁸ as it flattened mountain villages and destroyed buildings in the Himalayan region.

The injuries sustained during earthquakes are diverse. However crush injuries are the most common because of the collapse of buildings. Victims may sustain injuries due to falls during escape also. They usually sustain combination of injuries, including head and neck, chest, abdomen and extremities. A few patients may have isolated injuries.

Manipal Teaching Hospital is the only hospital in the western region to cater to neurosurgical patients. Patients were either directly flown in from the incident site or referred from other health care facilities after the initial treatment. In the western region, most affected areas were Barpak and Larpak in Gorkha district. Few patients came from Kaski, Tanahu, Lamjung and Parbat. Patients were

Study of Traumatic Brain Injury Due To Recent Earthquake in Manipal Teaching Hospital

The objective of this study was to review the demographics, causes injury, severity, treatment and outcome of traumatic brain injuries in victims of the April 2015 earthquake who were admitted in Manipal Teaching Hospital, Pokhara. A total of 37 patients was admitted under Neurosurgery Services. Collapse of buildings was the commonest cause of head injury. The majority of them had mild head injury. Associated injuries to other parts of the body were present in 40.54% patients.

Key Words: earthquake, extradural hematoma, head injury

brought to hospital on the same day for several days after the earthquake.

The objectives of the study were to find out data regarding the demographic status, type of craniocerebral trauma, treatment offered and outcome of head injuries.

Material And Methods

It was a hospital based observational study of all cases of head injury victims admitted in Manipal Teaching Hospital. Prospectively kept and filled pro forma were analyzed for demographic data regarding age and sex of the patients, time since the injury to hospital admission, cause of head injury, severity of traumatic brain injury based on the Glasgow Coma Score,⁹ findings on CT scan of the brain, treatment provided and outcome based on the Glasgow Outcome score.⁵ Outcome was measured at discharge. Ethical clearance was taken from an Institutional Review Board.

Sample size calculation

In a pilot study done prior to the original study with 10 patients showed Collapse of buildings was the commonest cause of injury in 7 out of 10 patients (70%). With 15% absolute precision and 95% Confidence interval required sample size was 35.

Figure 1: CT scan showing left frontal compound fracture and contusions

Figure 2: CT scan showing left sided chronic subdural hematoma

Results

There were 37 patients in total who were admitted for craniocerebral injuries. Among them, twenty six patients were brought from Gorkha district, the most affected district in this region.

Age and Sex of Patients

There were 18 males (48.65%) and 19 females (51.35%) patients. There were patients of all age groups. The age distribution of patients is shown in fig 1. Mean age of patients was 34.25 years (range 2-85 yrs).

Cause of injuries

Collapse of buildings was the commonest cause of injury in 24 patients (64.86%), followed by a fall during escape in 9 patients (24.32%). Two patients (5.41%) had injuries related to motor vehicle accidents and two patients (5.41%) sustained an injury due to fall from the tree during the shaking.

Severity of head injuries

Twenty nine patients (78.38%) had mild head injuries, 6 patients (16.21%) had moderate head injuries and 2 patients (5.41%) had severe head injuries.

CT scan findings

CT scan was normal in twenty patients (54.05%). There were skull fractures in 10 patients (27.02%), (Figure 1) intracranial hematomas in 8 patients (21.62%)

and pneumocephalus in 3 patients (8.15%). Extradural hematoma was in 2 patients, subdural hematomas in 3 patients (Figure 2) and contusions in 3 patients.

Associated injuries

Fifteen patients (40.54%) had associated injuries to other parts of the body. Six patients had spinal injuries, 4 had rib fractures, 3 patients had facial injuries and 2 had abdominal visceral injuries.

Treatments offered

Eighteen patients (48.65%) underwent surgery, which included debridement and suturing of large scalp laceration in 3, spinal fixation in six patients, craniotomy and evacuation of hematomas in 6 patients and elevation of depressed fractures in 3. All associated injuries were treated non-operatively.

Time since the injury to hospital admission

Only two patients were brought on the day of the quake. On the following day, 8 patients were brought. The majority of patients, 25 patients were brought on the 3rd day. And 2 patients were brought several days later.

Outcome

Mean hospital stay was 11 days (range 4 – 36 days). The outcome was assessed at the time of discharge. At the time of discharge 30 patients (81.1%) had a good recovery, 2 patients (5.4%) had moderate disability, 3 patients (8.12%) had severe disability and one patient died. During

the hospital course, one 73 years old man with multiple intracerebral contusions died of pneumonia.

Discussions

Earthquake is the most important fatal natural disaster.³ It causes numerous deaths in crowded city regions and also in areas with buildings with weak structural quality. Deaths may occur on the site in 2/3 of the victims and 1/3 after the evacuation in hospitals.¹¹ Injuries resulting deaths are either multisystem or usually penetrating wounds. Deaths are more common in injured children and elderly.⁷ Multisystem injuries are important dimensions of injury following earthquake.

In earthquakes, head injuries range from 3.2% to 61% and incidence of reported spinal trauma ranges between 4.9% and 31.1%.⁸ Head injuries have been extensively studied in previous earthquakes in Taiwan,⁷ Pakistan,² China,^{6,12} and Turkey.¹

In the study done by Bhatti SH et al⁹ in 2005 October earthquake in Pakistan, children less than 10 years constituted 41% and more than 55 years constituted 36% of all patients. Mild head injury occurred in 55%, moderate head injury in 35%, severe head injuries in 10% of patients. Conservative treatment was carried out in 48.7%, minor surgery in 17% and major surgery in 34.3% of the patients. Mortality at 6 months was 3.3%.

In the study done by Lu Jia et al¹⁰ in Sichuan earthquake in 2008 in China, among all head injured patients, scalp injuries was present in 65%, skull fractures in 28% and intracranial hematomas in 10%. Mild, moderate and severe head injuries occurred in 71%, 17% and 12% of head injured patients respectively. First day 18%, second day 35%, third day 29%, fourth day 18%

In the study done by Yang CH et al¹¹ in 2008 Wenchuan earthquake in China, male female ratio of patients was 1.7:1. Mild, moderate and severe head injuries occurred in 80, 12 and 8% of all head injuries. Collapse of building was the commonest cause of head injuries in this study. Open head injuries accounted for 60.8%. Operative procedures were carried out in 56%. Good recovery was achieved in 82.43% patients, moderate disability in 8.27%, severe disability in 5.55%, coma in 2.26% and death in 1.5%. In the study of neurosurgical injuries done by Aycan A et al¹² in 2011 Van earthquake in Turkey: head injuries were isolated in 90.9% and were associated with spinal injuries in 9.1%.

The findings of our study were similar to other studies done by Bhatti SH and Wang CH.

Traumatic Brain Injury

Human beings do not have the ability to prevent earthquakes. The delayed arrival of rescue and medical units along with severe infrastructure problems strain the emergency medical services and hospital based facilities. It will have a major impact on the chances of survival of seriously injured and trapped. However, we can take measures to minimize injuries and damage by using strict building codes and constructing infrastructures in areas of less risk.

Conclusions

In this study most of head injuries sustained by the victims were mild head injuries. Most were isolated injuries. The majority was rescued later as the areas were inaccessible. The majority had good outcomes
